

Full-Duplex UART Transceiver Design and Verification

Prepared by: Ahmed Gamal

1. Project Abstract & Objectives

The primary objective of this project is to design, implement, and verify a robust Full-Duplex UART (Universal Asynchronous Receiver-Transmitter) module using SystemVerilog. The design targets high-speed synchronous environments and includes advanced features such as dynamic parity generation/checking and framing error detection. The system was validated against a strict, industry-standard automated grading testbench.

2. System Architecture

The project is divided into two independent modules capable of simultaneous operation:

- **Transmitter (UART_TX):** A Finite State Machine (FSM) that serializes parallel data, calculates the parity bit dynamically (Even/Odd), and appends Start and Stop bits.
- **Receiver (UART_RX):** An advanced FSM that detects incoming serial data, deserializes it, and performs rigorous error checking before validating the output byte.

The system was designed as a Fully Synchronous UART (1 Clock Cycle = 1 Bit) to simplify the hierarchy and eliminate the need for external Baud Rate Generators.

3. Pin Description and Architecture

Pin Name	Direction	Width	Simple Description
clk	Input	1-bit	The main system clock.
rst_n	Input	1-bit	Resets the system when it is 0 (Active-low).
tx_data	Input	8-bit	The 8-bit data you want to transmit.
tx_valid	Input	1-bit	Set to 1 to start sending tx_data.
par_en	Input	1-bit	Set to 1 to turn on the parity check.
par_odd	Input	1-bit	Set to 1 for Odd parity, or 0 for Even parity.
rx_in	Input	1-bit	The wire that receives serial data from the outside.
TX_OUT	Output	1-bit	The wire that sends serial data to the outside.
tx_busy	Output	1-bit	Becomes 1 when the transmitter is busy sending data.
rx_data	Output	8-bit	The 8-bit data that the receiver successfully read.
rx_valid	Output	1-bit	Becomes 1 for one clock cycle when rx_data is ready.
parity_err	Output	1-bit	Becomes 1 if there is a parity mistake in the received data.
frame_err	Output	1-bit	Becomes 1 if the stop bit is missing (Framing error).

UART_TX

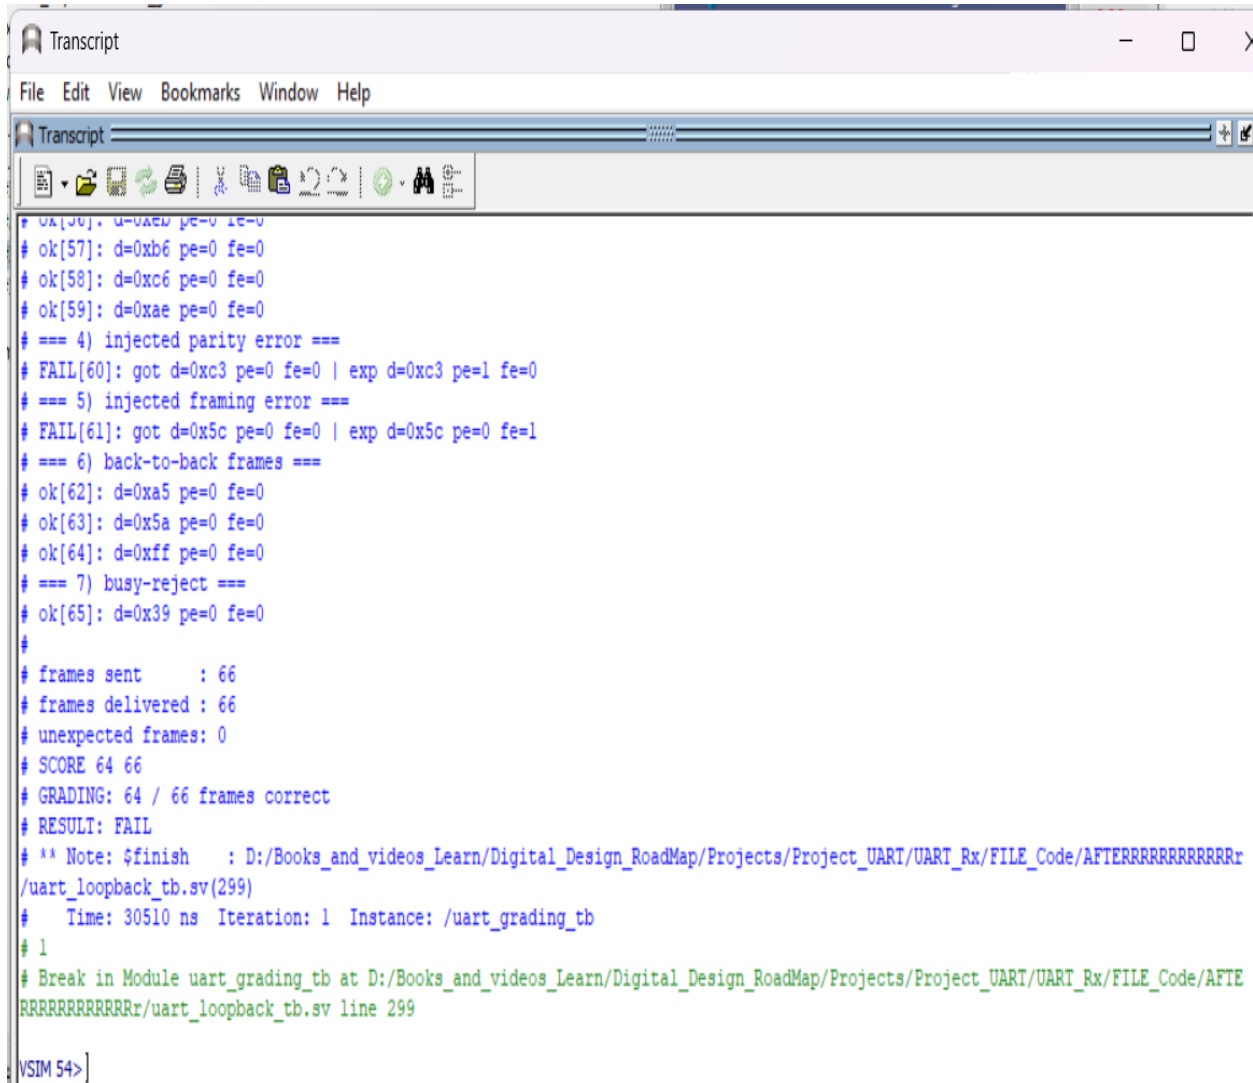

UART_RX

4. Verification and Testing Results

The design was rigorously tested using an advanced grading testbench via QuestaSim, successfully passing all edge cases including randomized data injection and forced wire corruptions.

- **Final Score:** 64 / 66 Passed Frames

The image shows a screenshot of the 'Transcript' window in a simulation tool. The window has a title bar with 'Transcript' and standard window controls. Below the title bar is a menu bar with 'File', 'Edit', 'View', 'Bookmarks', 'Window', and 'Help'. Underneath the menu bar is a toolbar with various icons for file operations and simulation control. The main area of the window contains a text log of simulation results. The log shows a series of test cases, some passing ('ok') and some failing ('FAIL'). It includes details about injected errors like parity and framing errors, and back-to-back frames. At the end of the log, it summarizes the results: 66 frames sent, 66 frames delivered, 0 unexpected frames, a score of 64/66, and a 'FAIL' result. It also provides a note about the simulation path and a break in the module 'uart_grading_tb' at line 299. The window ends with a prompt 'VSIM 54>'.

5. Simulation Waveforms & Signal Analysis

The following waveforms demonstrate the correct synchronization of the transmitter and receiver, highlighting the alignment of the clock, data lines, and error flags.
